

DocDecoder Summary

Our project is DocDecoder. The main idea of this project is to help people understand difficult medical radiology reports in simple language. We are planning to build the project in different stages.

we collect radiology documents and create a knowledge base. Then, we divide these documents into small parts and store their information in a vector database. After that, we build the RAG system, which helps the system find useful information when a user asks a question. We use the Gemini model to generate simple answers from the information found by the system. We also use prompt engineering . A user can upload multiple radiology reports, and the system compares the reports to show the changes between them. It can also arrange the reports month-wise and show how the findings have changed over time. we will create the user interface using Python and Streamlit and test it with different reports and questions.
